

Modeling Critical Temperatures of Superconductors

Allen Wu

Background

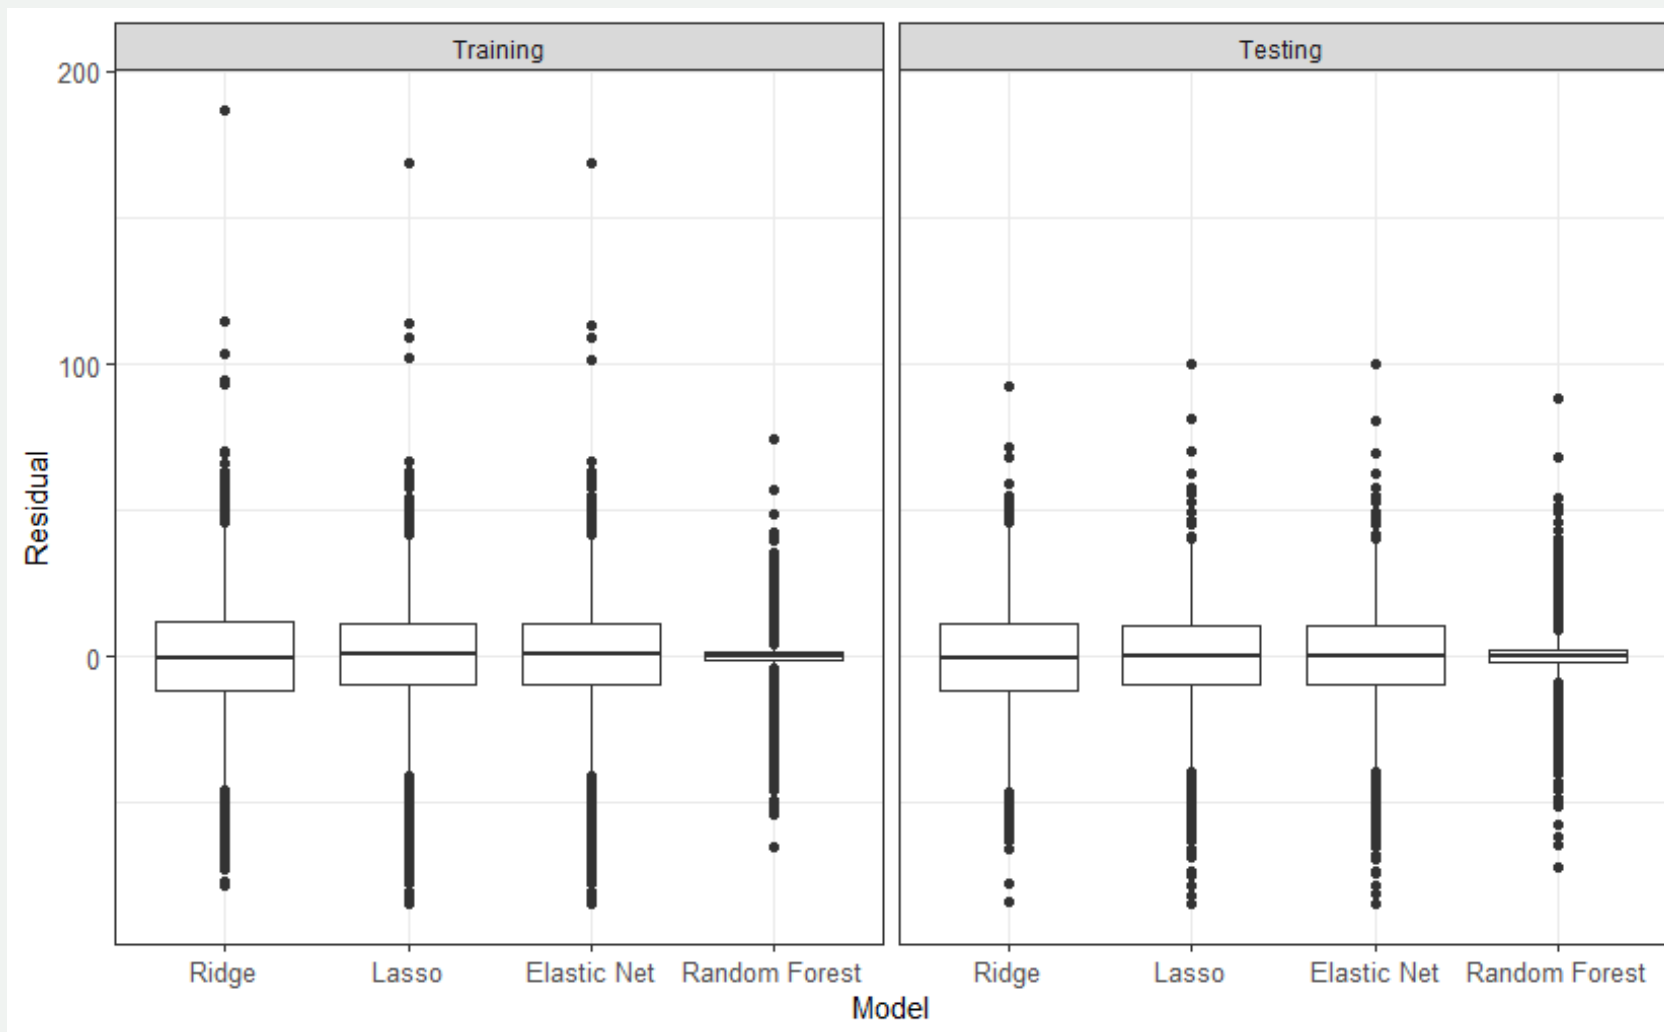

- 21263 different superconductors
- 81 features
 - Number of unique elements
 - Atomic mass
 - Atomic radius
- Response variable: superconductor's critical temperature
- Zero electrical resistance if cooled to critical temperature
- Most critical temperatures are very low
- Used in MRI machines, maglev trains, particle accelerators

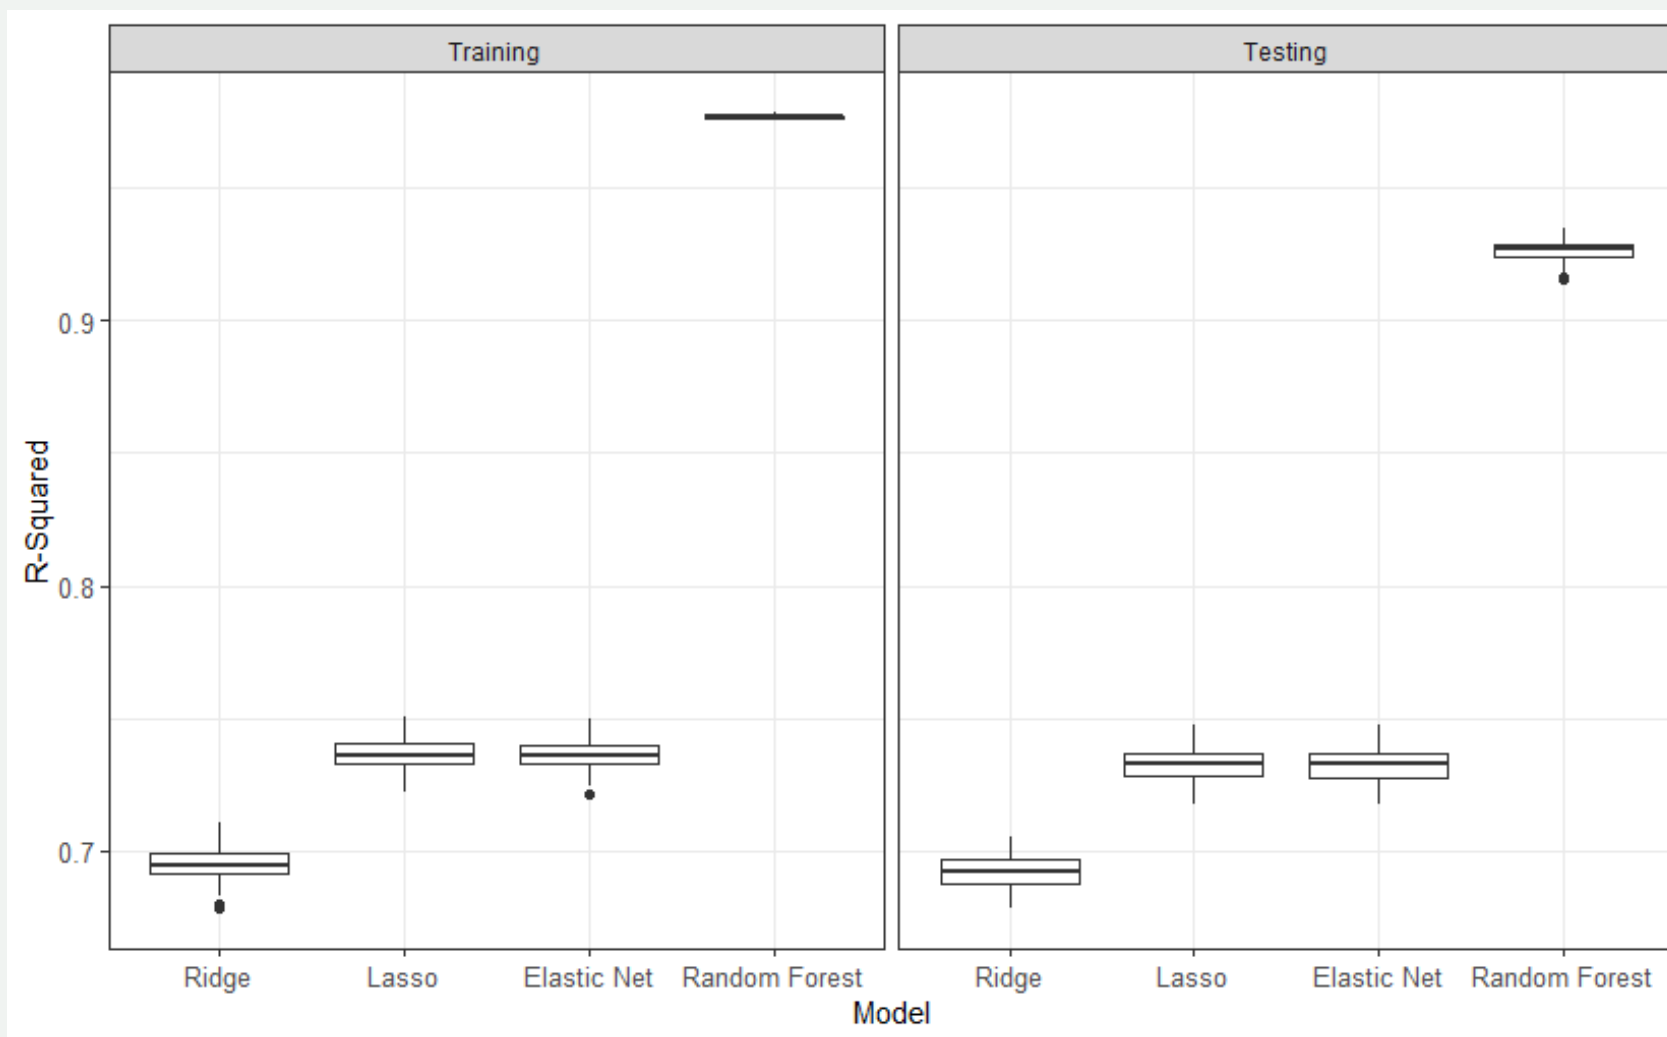

Cross Validation Curves

Residuals

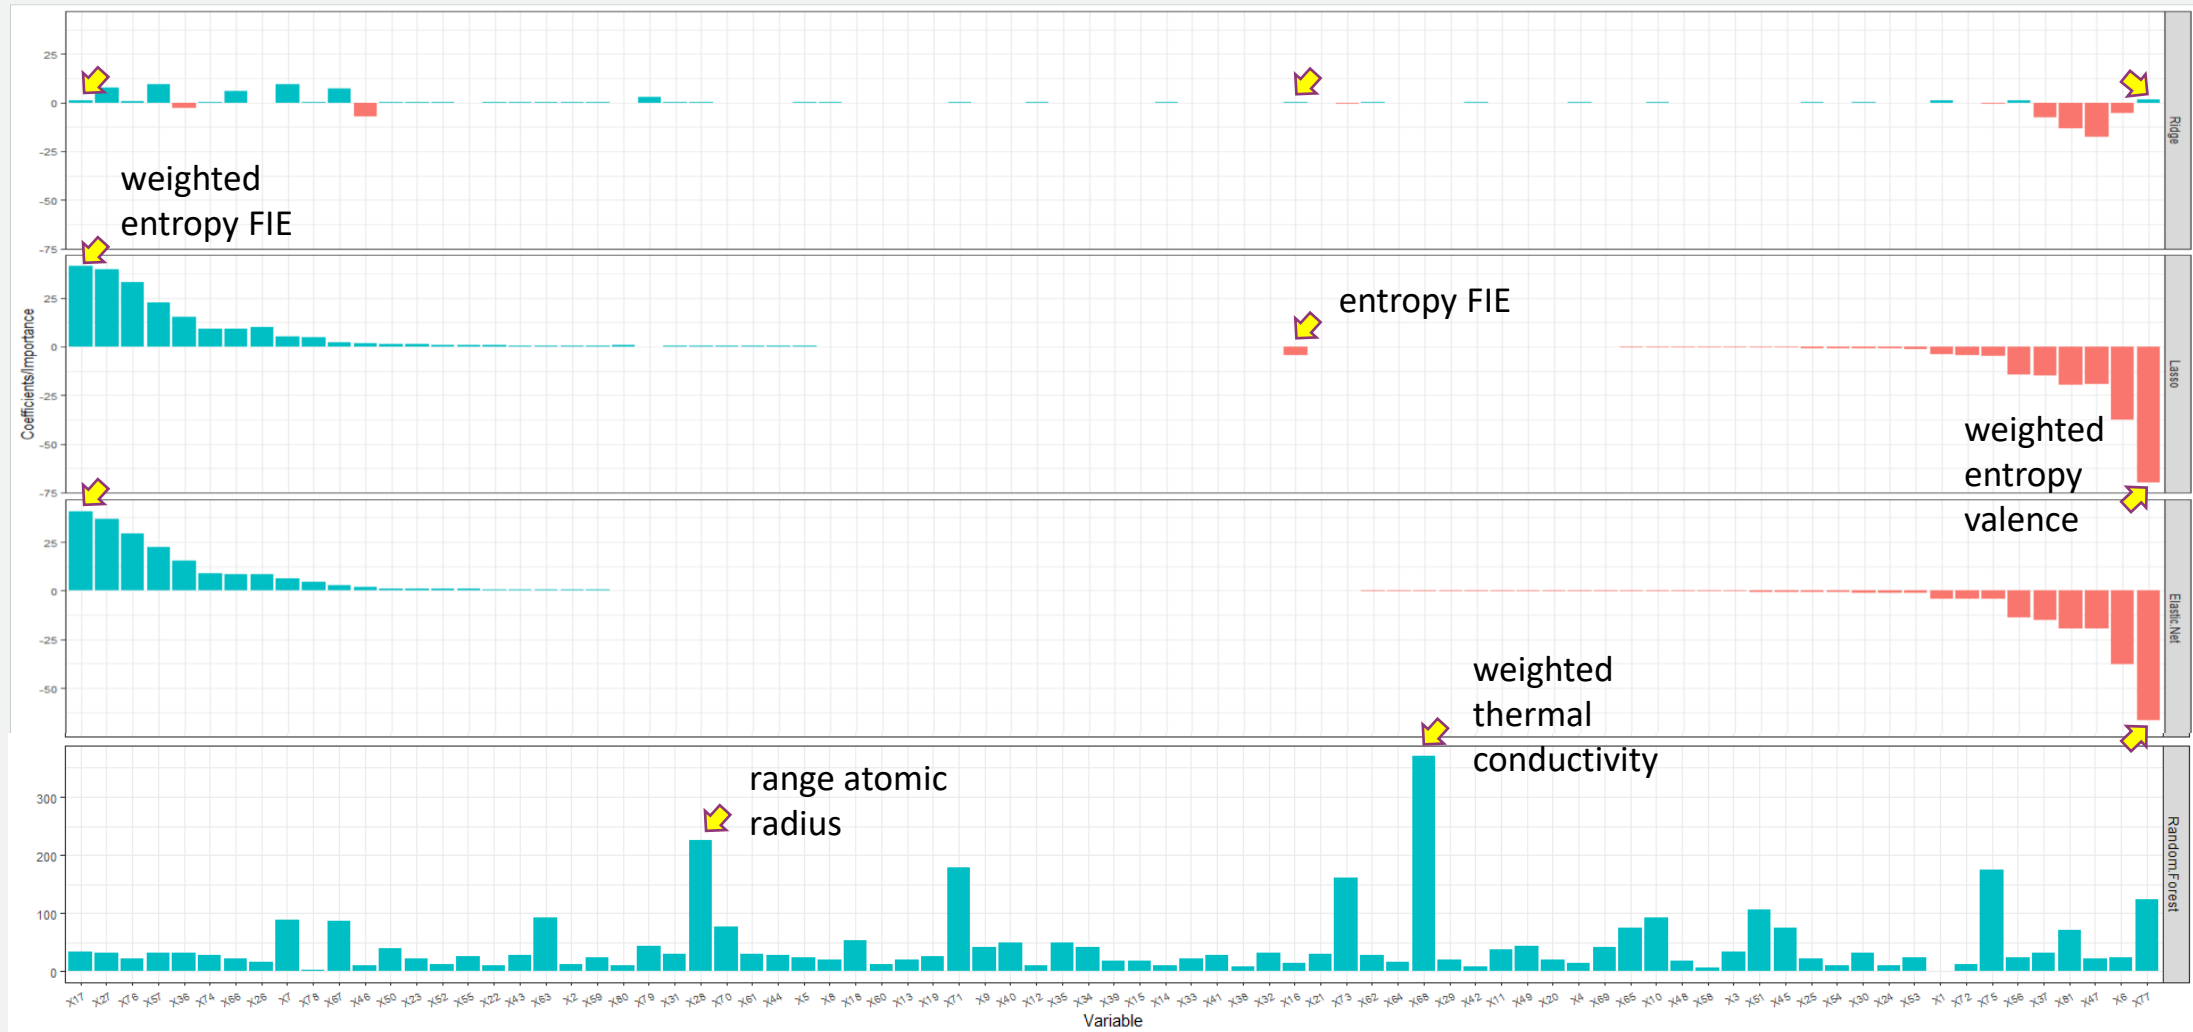

R-Squared

Intervals and Runtime

Model	90% Test R^2 Interval	Runtime on Entire Dataset
Ridge	0.68-0.70	1.4 secs
Lasso	0.72-0.74	1.3 secs
Elastic Net	0.72-0.74	1.2 secs
Random Forest	0.92-0.93	840 secs

Beta Coefficients and Importance

Conclusion

- Decision tree model performs much better than regression in predicting critical temps
- Huge tradeoff in time vs accuracy between tree-based and regression models
- Tradeoff not an issue once a model is developed
- These models cannot predict if a material is a superconductor
